Art Unit: 2878

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

Claims 1-4 and 7-10 are rejected under 35 U.S.C. 103(a) as being unpatentable over Munakata in view of Kato et al. and Ichihashi et al.. Munakata discloses a method and apparatus for generating an image of a specimen comprising a voltage applying means 15 which applies a voltage to a sample 6 while an electron beam 16 is scanned across the sample and the resultant current induced in the sample by the electron beam is detected and correlated with the position of the electron beam to generate an image of the sample. Kato et al. teaches that such apparatus can be used to measure distances between points on the sample. One of the measurement methods taught by Kato et al., as summarized at lines 26-30 in column 2, involves determining the position of a mark on the sample image by measuring the delay between a beam scanning start time and the time at which the scanning electron beam reaches the position represented by the mark. According to Kato et al., the size of any given feature on the specimen can be measured by making a mark on opposing edges of the feature and measuring the distance between the two marks. Ichihashi et al. teaches that instead of the operator arbitrarily choosing two marks to indicate a distance to be measured, means can be provided to select the opposing edges by detecting the changes in the signals generated by the interaction of the electron beam and the specimen. While both Kato et al. and Ichihashi et al. illustrate embodiments of their inventions wherein either secondary or

Art Unit: 2878

reflected electrons are detected, both patents state (Kato et al. at lines 11-20 in column 1 and Ichihashi et al. at lines 5-8 in column 3) that any signal generated by the interaction of the electron beam and the specimen can be used. Munakata teaches at lines 27-32 in column 1, that specimen currents are known in the art to be equivalent to back-scattered or secondary electrons for purposes of detection in scanning electron microscopes to indicate the interaction of an electron beam with a specimen. It would therefore have been obvious to a person having ordinary skill in the art to use Kato et al.'s measuring system to measure distances between points observed using the Munakata scanning electron microscope with changes in the detected signals being used to indicate the points to be measured, in the manner taught by Ichihashi et al..

Claims 5 and 11 are rejected under 35 U.S.C. 103(a) as being unpatentable over Munakata, Kato et al., and Ichihashi et al. as applied to claims 1-4 and 7-10 above, and further in view of Todokoro et al.. Todokoro et al. teaches at lines 56 in column 1 through 14 in column 2 that the presence of passivation layers on integrated circuits creates a capacitance which prevents the observation of DC voltages in the integrated circuits by scanning electron microscopes. According to Todokoro et al., the way to overcome this problem is to periodically vary the bias voltage applied to the integrated circuit sample. It would therefore have been obvious to a person having ordinary skill in the art to periodically vary the bias voltage applied to the sample in the Munakata/Kato et al./Ichihashi et al. method and apparatus discussed above in order to overcome the capacitance problem disclosed by Todokoro et al..

Art Unit: 2878

Claims 6 and 12 are rejected under 35 U.S.C. 103(a) as being unpatentable over Munakata, Kato et al., and Ichihashi et al. as applied to claims 1-4 and 7-10 above, and further in view of Migitaka et al.. Migitaka et al. teaches to improve the signal-to-noise ratio of a scanning electron microscope by detecting secondary electrons and reflected electrons as well as an absorption current and combining at least two of these signals. It would have been obvious to a person having ordinary skill in the art to provide means to detect secondary electrons and/or reflected electrons in the Munakata/Kato et al./Ichihashi et al. method and apparatus discussed above in order to improve the signal-to-noise ratio in the manner taught by Migitaka et al..
